**(54) Compact circuit carrier package**

(57) A circuit carrier assembly includes a plurality of substrates directly secured together by an electrically conductive securing substance. In one example, the securing substance is a conductive epoxy. In another example, the electrically conductive securing substance is solder. Still another example includes a combination of solder and conductive epoxy. A non-conductive epoxy provides further mechanical connection and thermal

conductivity between the substrates while also electrically isolating selected portions of the substrates in one example. The electrically conductive securing substance not only mechanically secures the substrates together and provides thermal conductivity between the substrates, which increases the thermal capacitance of the assembly, but also establishes at least one electrically conductive path between the substrates.

**FIG. 2**

**EP 1 355 353 A2**

## Description

### BACKGROUND OF THE INVENTION

[0001] This invention generally relates to circuit carrier assemblies having more than one component-supporting substrate. More particularly, this invention relates to circuit carrier assemblies have a conductive securing substance securing a plurality of substrates together to establish an electrically conductive path between the substrates.

[0002] There are a variety of ways of assembling power modules for circuit carrier assemblies. Typical arrangements include generally planar substrates aligned beside each other, often in a co-planar orientation. A housing typically is provided over at least portions of the substrates. The housing typically operates to mechanically secure the substrates into positions relative to each other as needed.

[0003] Electrical connections between the substrates typically are achieved by soldering pins between pads on the substrates. Such electrical connections, while establishing effective conductive paths, have the drawback of increasing the size of the overall package. Additionally, a shortcoming of the conventional electrical connections is that they did not provide any thermal or mechanical connection between the substrates.

[0004] There is a need for an improved arrangement. In many industries, size constraints are becoming increasingly important. Lighter weight, more compact power modules or circuit carrier assemblies are necessary to meet current industry demands.

[0005] This invention addresses that need, avoids the shortcomings and drawbacks of the prior art and presents a beneficial improvement.

### SUMMARY OF THE INVENTION

[0006] In general terms, this invention is a circuit carrier assembly that has an electrically conductive connector securing a plurality of substrates together such that the connector provides a mechanical connection between the substrates that also provides for electrical conductivity between the substrates.

[0007] In one example, the substrates have at least one feedthrough opening and the electrically conductive connector is positioned relative to the feedthrough openings such that at least one conductive path between the substrates is established and accessible through the feedthrough openings.

[0008] In one example, the conductive connector is a securing substance such as an epoxy. In another example, the conductive connector comprises securing solder. In still another example, the connector comprises a wire bond. Depending on the type of substrate and other manufacturing considerations, the conductive connector may comprise a conductive epoxy, solder, a wire bond or a combination of any two or more of the three.

[0009] The connector of the inventive arrangement not only mechanically secures the substrates together, but also establishes at least one electrically conductive path between the substrates. The examples that include a securing substance such as solder or epoxy also provides for thermal conductivity between the substrates, which increases the heat dissipation capacity of the assembly.

[0010] In one example, a non-conductive epoxy is provided on at least a portion of the substrates to mechanically secure the substrates together, provide electrical isolation between the substrates at the corresponding portions while also providing for thermal conductivity between the substrates.

[0011] The inventive arrangement provides substantial improvement in that the overall size of the assembly is reduced, thermal dissipation capacity is increased and circuit density is increased. In one example, the inventive arrangement is more than fifty percent smaller than a conventional assembly, seventy percent lighter with a greater than forty percent decrease in power dissipation.

[0012] The various features and advantages of this invention will become apparent to those skilled in the art from the following detailed description of the currently preferred embodiments. The drawings that accompany the detailed description can be briefly described as follows.

### BRIEF DESCRIPTION OF THE DRAWINGS

#### [0013]

Figure 1 schematically illustrates a circuit carrier assembly designed according to this invention.

Figure 2 is a top planar view of an example assembly designed according to this invention.

Figure 3 is a cross sectional illustration taken along the lines 3-3 in Figure 2.

Figure 4 is a cross sectional illustration similar to Figure 3 but showing another embodiment of this invention.

### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0014] Figure 1 schematically illustrates a circuit carrier assembly 20 including a first substrate 22 and a second substrate 24. The first substrate 22 has one side 26 facing toward the second substrate 24. Likewise, the second substrate 24 has a side 28 facing the first substrate 22.

[0015] The substrates 22 and 24 are mechanically secured together by a conductive connector, which in this example comprises securing substance 30. The illustrated example includes conductive portions 32, 34 and 36 (as visible in the illustration) that provide at least one electrically conductive path between the substrates 22

and 24. The electrically conductive securing substance 30 in one example comprises a conductive epoxy. A variety of such epoxies are commercially available and, given this description, those skilled in the art will be able to select a suitable one to meet the needs of their particular situation.

**[0016]** In another example, the electrically conductive securing substance 30 comprises solder. Soldering the substrates 24 and 22 together provides a mechanical connection between the substrates while also establishing at least one conductive path between them.

**[0017]** In another example, a combination of a conductive epoxy and solder is used as the electrically conductive securing substance 30.

**[0018]** As can be appreciated from the drawings, the electrically conductive securing substance need not extend across the entire surface of either substrate. Instead, the electrically conductive securing substance may be strategically placed at portions between the substrates where electrically conductive paths are desired.

**[0019]** The illustrated example of Figure 1 includes a non-conductive epoxy 40 providing a further mechanical connection between the substrates 22 and 24. The non-conductive epoxy 40 and the electrically conductive securing substance 30 not only provide a mechanical connection between the substrates but also establish thermally conductive connections between the substrates. Coupling the substrates together in this manner increases the thermal dissipation capacity of the assembly.

**[0020]** As can best be appreciated from Figures 2 and 3, each substrate preferably is capable of supporting one or more circuit components. In the illustrated example, a microprocessor 44 and a plurality of other components 45 are supported on the first substrate 22. A conventional frame 46 covers a chip and wire section 47 on a portion of the substrate 22. The type of components selected will depend on the needs of a particular situation. The circuit components are supported on the side of the substrate facing away from the adjacent substrate 24.

**[0021]** The substrate 24 supports a plurality of components such as field effect transistors (FET) 48. In the illustrated example, the FET's 48 are electrically coupled to the conductive securing substance 30 using a wire bond 50. Other electrically conductive connections may be used.

**[0022]** The substrates 22 and 24 include a plurality of feedthrough openings 52 that allow the electrically conductive securing substance 30 to be accessible on the outward facing sides of the substrates. This permits a coupling such as the wire bond 50 to link the FET 48 to a desired portion of the circuitry supported on the substrate 22. In this manner, the electrically conductive securing substance 30 establishes an electrically conductive path in a direction perpendicular to the surfaces of the substrates 22 and 24.

**[0023]** While the illustrated example includes a plurality of feedthrough openings 52 on the substrates, it is

preferred to place conductive epoxy or solder (i.e., the electrically conductive securing substance 30) only in the vicinity of feedthrough openings where electrically conductive connections are desired.

**[0024]** In situations where only a few such electrically conductive paths are required, a non-conductive epoxy 40 provides further mechanical connection between the substrates and increases the thermal conductivity between the substrates.

**[0025]** While the illustrated example includes the feedthrough openings 52 to establish the electrically conductive path between the substrates, it is possible to include the securing substance 30 close enough to the exterior perimeter of the substrates so that a connection could be made along the outside of the package. Feedthrough openings through the substrates are preferred so that the integrity of the electrical connections is better protected during shipment or handling of the assembly, for example.

**[0026]** The illustrated example includes adhesive 54 securing a housing portion 56 to the substrate 24 to cover over at least selected circuit components on the substrate 24. In the illustrated example, the housing 56 protects the wire bonds 50, for example.

**[0027]** In the example of Figure 3, the portion above the broken reference line 70 can be considered the control section of the assembly 20. The portion below the line 70 can be considered the power section. Conventional gull wing style terminals 72 facilitate connecting the assembly 20 as needed.

**[0028]** The example of Figure 4 shows a conductive connector that includes a wire bond 80. The illustrated example has the wire bond 80 secured to the substrate 22 and a portion of conductive epoxy 30, respectively. The epoxy 30 electrically couples the wire bond 50 to the wire bond 80 so that an electrically conductive path is established.

**[0029]** Wire bonding is a preferred connection method where a highly reliable connection is desired. Example situations are aircraft applications where vibration levels are high. Another example situation is where a high number of thermal cycles occur.

**[0030]** The substrates 22 and 24 may comprise a variety of materials including direct copper bonded substrates, thick film ceramic substrates and others. The selection of substrate material will depend, in part, on the desired thermal capacitance of the assembly and the particular circuitry involved for a particular application.

**[0031]** The inventive arrangement presents a substantial improvement over conventional assemblies because the size of the assembly is greatly reduced, in one example, by more than fifty percent. The weight of the overall assembly in one example is at least seventy percent lighter than a conventional assembly having similar circuit characteristics. Not only is the thermal capacitance and circuit density of the assembly increased, but the power dissipation is reduced compared to con-

ventional arrangements, in one example more than forty percent.

[0032] The preceding description is exemplary rather than limiting in nature. Variations and modifications to the disclosed examples may become apparent to those skilled in the art that do not necessarily depart from the essence of this invention. The scope of legal protection given to this invention can only be determined by studying the following claims.

## Claims

1. A circuit carrier assembly, comprising:

a first generally planar substrate;  
a second generally planar substrate aligned generally parallel with the first substrate; and  
an electrically conductive connector securing the first substrate to the second substrate and establishing at least one electrically conductive path that extends between the substrates.

2. The assembly of claim 1, wherein the connector comprises at least one of a conductive epoxy or solder.

3. The assembly of claim 1, including a nonconductive epoxy securing at least selected portions of the substrates together and providing a thermally conductive and electrically isolated connection between the corresponding portions of the substrates.

4. The assembly of claim 1, including at least one feedthrough opening positioned relative to at least a portion of the securing substance and the feedthrough opening on an adjacent one of the substrates such that the at least one conductive path is established by at least the portion of the securing substance accessible through the feedthrough openings, respectively.

5. The assembly of claim 1, wherein the connector comprises a wire bond establishing the at least one conductive path.

6. A method of assembling a plurality of generally planar circuit carrier substrates, comprising the steps of:

aligning the substrates in a desired non-coplanar orientation; and  
securing the substrates directly to each other by placing an electrically conductive securing substance between the substrates such that the securing substance establishes at least one electrically conductive path between the substrates.

7. The method of claim 6, wherein the securing substance comprises at least one of a conductive epoxy or solder.

8. The method of claim 6, wherein the securing substance comprises an electrically conductive epoxy.

9. The method of claim 8, including securing the substrates to each other using a nonconductive adhesive.

10. The method of claim 9, including securing the substrates to each other by soldering at least a portion of each substrate to the other.

11. The method of claim 6, wherein the securing substance comprises solder.

12. The method of claim 6, wherein each substrate includes at least one feedthrough opening positioned relative to the feedthrough opening of an adjacent substrate and a corresponding portion of the securing substance and including establishing the electrically conductive path through the feedthrough openings.

13. The method of claim 6, wherein the securing substance establishes a thermal connection between the substrates.

14. A circuit carrier assembly, comprising:

a plurality of substrates that are secured to each other by a securing substance that comprises at least one of a conductive epoxy or solder, each substrate having at least one feedthrough opening positioned relative to at least a portion of the securing substance and a feedthrough opening on an adjacent substrate such that an electrically conductive connection is established between the substrates by at least the portion of the securing substance accessible through the feedthrough openings, respectively.

15. The assembly of claim 14, including a nonconductive epoxy bonding at least one other portion of the substrates to each other, the nonconductive epoxy being operative to electrically isolate at least the other portion of the substrates.

16. The assembly of claim 14, including a nonconductive epoxy bonding at least one other portion of the substrates to each other, the nonconductive epoxy being operative to transfer heat between the substrates.

17. The assembly of claim 14, wherein at least one of

the substrates includes at least one circuit component supported at least partially on the substrate, and wherein the circuit component is electrically coupled with the portion of the securing substance establishing the electrically conductive connection. 5

18. The assembly of claim 17, wherein wire bonding couples the circuit component to the portion of the securing substance. 10
19. The assembly of claim 14, including at least one wire bond electrically connecting the substrates.
20. The assembly of claim 14, wherein the securing substance comprises the conductive epoxy and solder. 15
